

One Algo, and a floor that rises 16,000 μA per signature

Magnified: the last step that fits, and the first that does not

Nothing here is a bug in the contract's logic. The contract does on the fifty-sixth signature exactly what it did on the first; what changed is a number kept outside it, in the ledger, by a rule the code never mentions. That is why the fix is a check the code makes before it writes.

Both plots are to scale. In the main plot the two steps the whole story turns on are five and a half pixels apart, which is why the inset has to exist.
