}
```

- 1 Which transaction in the group failed. Zero-indexed, so this is the third one.
- 2 The assert that fired. Everything above it in the program had already run.
- 3 The program counter. Feed it to the source map puyapy wrote beside the TEAL and it becomes a line number in your own file.
- 4 Opcode budget actually consumed: 683 of 700. One more loop iteration and this call fails for an entirely different reason.
- 5 Why simulate could run it at all — it takes unsigned transactions. That is exactly what makes it usable for negative tests.

The request succeeded. The group did not. A test that asserts on the status code and stops there can never fail, no matter what the contract does — read failure-message, or assert nothing at all.
